RESEARCH MEMORANDUM

A COMPARISON OF THE CHORDWISE PRESSURE DISTRIBUTION AND
SPANWISE DISTRIBUTION OF LOADING AT SUBSONIC SPEEDS
ON TWO TRIANGULAR WINGS OF ASPECT RATIO 2
HAVING NACA 0005 AND 0008 SECTIONS

By Donald W. Smith and Verlin D. Reed

SUMMARY

An investigation has been made to determine the effects of a change in section thickness on the surface pressures, forces, and moments of two wing-body combinations having triangular wings of aspect ratio 2. The wing sections, in the streamwise direction, were the NACA 0008-63 and the NACA 0005-63. The measurements were made over a range of Mach numbers from 0.11 to 0.95 at a constant Reynolds number of 3.0 million. Data were also obtained at Reynolds numbers up to 15.0 million at the lower Mach numbers.

The effect of a reduction in wing thickness on the chordwise distribution of pressure and on the span-loading characteristics was investigated. A comparison was made between the span-loading characteristics computed by the slender-body theory of Spreiter, the Weissinger theory, and those calculated from the measured pressure distributions. A decrease in wing thickness from 8 percent to 5 percent did not appreciably change the span-loading characteristics, and at low values of lift coefficient the experimental data were in good agreement with theory. In general, for Mach numbers up to about 0.80, the reduction of thickness decreased the lift coefficient at which extensive regions of flow separation occurred.

A comparison was also made between the data obtained from force tests of each of the wings. The reduction of wing thickness had little effect on the maximum lift-drag ratio for the Mach numbers below 0.90. At a Mach number of 0.95 the maximum lift-drag ratio was about 16 percent greater for the thinner wing. The lift coefficient at which the maximum lift-drag ratio was attained was reduced by the reduction in thickness.

~~CONFIDENTIAL~~

for all but the highest Mach numbers. For lift coefficients of 0.2 and above at Mach numbers below 0.80, the reduction of wing thickness generally increased the drag.

INTRODUCTION

Research is in progress at the Ames Aeronautical Laboratory to ascertain experimentally, at subsonic and supersonic Mach numbers, the characteristics of wings of interest in the design of high-speed fighter airplanes. The effects on the wing characteristics of variations in plan form, twist, camber, and thickness are being investigated. Two of the models being tested in this program had a plane, triangular wing of aspect ratio 2. The wing sections, parallel to the air stream, of one of the models were the NACA 0008-63, while those of the other were the NACA 0005-63. The lift, drag, and pitching moment of these two models are presented in references 1 and 2. The effect of the change in wing thickness on the chordwise and spanwise distribution of loading as well as on the forces and moments was considered to be of interest to the aircraft designer. This report presents the results of pressure-distribution measurements made at subsonic speeds on the two wing-body combinations previously mentioned. Some of the results of tests previously reported in references 1 and 2 are also included in this report.

NOTATION

b wing span, feet

$\frac{c_{nc}}{C_N c_{av}}$ loading coefficient for the linear portion of both the section
normal-force curve and the total normal-force curve

APPARATUS

Wind Tunnel and Equipment

The experimental investigations were conducted in the Ames 12-foot low-turbulence pressure wind tunnel. In this wind tunnel the Mach number can be varied continuously and the stagnation pressure can be regulated to maintain a given test Reynolds number. Formation of condensation shocks is prevented by drying the air in the tunnel. More detailed information concerning the tunnel may be obtained from reference 3.

The models were sting mounted and the pressure tubes were enclosed within the sting. In this installation, the diameter of the sting was about 85 percent of the diameter of the body base. A balance mounted on the sting support and enclosed within the body of the model was used to measure the aerodynamic forces and moments on the model. The balance was the 4-inch-diameter, four-component, strain-gage balance described in reference 4.

Model

A photograph of the model mounted in the wind tunnel is shown in figure 1. A plan view and front view of the models and certain model dimensions are given in figure 2. Other important geometric characteristics of the models are as follows:

~~CONFIDENTIAL~~

Wing

Aspect ratio	2
Taper ratio	0

Thicker model	NACA 0008-63
Thinner model	NACA 0005-63
Total area, S , square feet	4.014
Mean aerodynamic chord, \bar{c} , feet	1.889
Dihedral, degrees	0
Camber	None
Twist, degrees	0
Distance, wing-chord plane to body axis, feet	0

Body

Fineness ratio (based upon length, l , fig. 2)	12.5
Cross-section shape	Circular
Maximum cross-sectional area, square feet	0.204
Ratio of maximum cross-sectional area to wing area	0.0509

An alloy of tin and bismuth was bonded to a steel spar to form the wing contours, while the contour of the fuselage was formed by use of aluminum castings over a steel spar. The surfaces of both the wings and body were polished to a smooth finish.

The pressure measurements were made on the left half of the wing. Eighty-three orifices were located in five chordwise rows along the top and bottom surfaces of the exposed portion of the wing as shown in figure 3. Fourteen additional orifices were located along the top and bottom center lines of the fuselage. The chordwise locations of the orifices for both wings are also presented in figure 3.

The ordinates for the NACA 0008-63 and the NACA 0005-63 airfoil sections are presented in table I.

TESTS AND PROCEDURE

Range of Test Variables

The chordwise pressure distribution on the models as a function of angle of attack was investigated for Mach numbers from 0.11 to 0.95 at a constant Reynolds number of 3.0 million. Data were also obtained at Reynolds numbers up to 15.0 million at the low Mach numbers.

Reduction of Data

The test data have been reduced to standard NACA coefficient form. Factors which affect the accuracy of these results and the corrections applied are discussed in the following paragraphs.

Tunnel-wall interference.- No corrections were made to the pressure data for the induced effects of the tunnel walls resulting from the lift on the models. The force data were corrected, according to the methods of reference 5, for the induced effects of the tunnel walls. No corrections were made to the pitching-moment coefficients.

The effects of constriction of the flow by the tunnel walls were taken into account by the method of reference 6. This correction was calculated for conditions at 0° angle of attack and was applied through the angle-of-attack range. At a Mach number of 0.95 this correction amounted to a 2 percent increase in the Mach number over that determined from a calibration of the tunnel without a model in place.

Stream variations.- Calibration of the 12-foot wind tunnel has shown that in the test region the stream inclination, determined from tests of a wing spanning the tunnel with the support system at 0° angle of attack, is less than 0.08° . The longitudinal variation of the static pressure in the region of the models is less than 0.2 percent of the dynamic pressure. No correction for the effect of these variations was made.

Support interference.- The effects of support interference on the pressure distributions of the models are not known. For the present models, it is believed that such effects consisted primarily of a change in the pressure at the base of the models.

RESULTS AND DISCUSSION

Effect of Wing Thickness

There are repeated in figure 4 some of the results reported in references 1 and 2. At lift coefficients less than about 0.30, reducing the wing thickness from 8 percent to 5 percent had little effect on the lift or pitching-moment characteristics of the model for subsonic Mach numbers from 0.24 to 0.95. At higher lift coefficients, the thinner wing produced greater lift at the same angle of attack, and at Mach numbers up to 0.80 the thinner wing had a more forward center of pressure. At a Mach number of 0.95, the center of pressure of the thinner wing was the more rearward at the higher lift coefficients. At Mach numbers of 0.24 and 0.40, the 5-percent-thick wing had considerably higher drag

than the 8-percent-thick wing at lift coefficients above 0.20. At a Mach number of 0.95, the thinner wing had the lower drag at all lift coefficients for which data were obtained.

There are presented in figures 5 through 8 representative data showing the effect of wing thickness on the chordwise distribution of pressure coefficient for Mach numbers from 0.24 to 0.95. The values of pressure coefficient are presented in tabular form for all test conditions. Table II is the index for the tabulations which are presented in tables III through XXXII.

An inspection of the chordwise pressure distributions (figs. 5 through 8) shows that the separation-vortex type of flow reported in reference 7 occurred on both wings. The occurrence of this type of flow was indicated by the formation of the low pressure bumps in the chordwise pressure distributions (e.g., fig. 5(c).) The separation vortex originated at a lower angle of attack for the thinner wing, as would be expected in the light of available data. Since a discussion of the separation vortex is presented in reference 7, no further discussion is deemed necessary here.

The section normal-force coefficients are presented in figure 9 as functions of uncorrected angle of attack for several Mach numbers. Section normal-force coefficients are also tabulated in tables III through XXXII for some test conditions. Due to the lack of sufficient pressure data, the section normal-force coefficient was not determined for the 0.90 semispan station of the 5-percent-thick wing.

At Mach numbers below 0.80 not all of the sections of the wings stalled; however, the sections of the 8-percent-thick wing which reached the stall did so at a higher angle of attack and a higher section normal-force coefficient than those of the thinner wing. At Mach numbers of 0.80 and above fewer sections stalled than at the lower Mach numbers due to the fact that sufficiently high angles of attack could not be attained. At these higher Mach numbers the stalled sections of the 8-percent-thick wing reached the stall at the same or a lower angle of attack than those of the 5-percent-thick wing.

At Mach numbers from 0.24 to 0.95 and at angles of attack below section stall, the thinner wing had approximately the same or higher section normal-force coefficients and consequently higher lift coefficients. This same effect of thickness can be seen from the force data of figure 4(a).

Effect of Reynolds Number

In figures 10 and 11 are shown the effects of Reynolds number on the aerodynamic characteristics of both wings at a Mach number of 0.24. These effects of Reynolds number were small but it should be noted that the effects on the 5-percent-thick wing were somewhat larger than on the 8-percent-thick wing. This was especially true of the effect on the drag coefficients. An increase in Reynolds number from 3.0 million to 15.0 million caused a slight increase in the maximum lift-drag ratio for both wings. There was also an increase, due to the increase of Reynolds number, of the lift coefficient at which the maximum lift-drag ratio was attained for both wings.

The changes in chordwise distribution of pressure due to an increase of Reynolds number from 3.0 million to 15.0 million at a Mach number of 0.24 are shown in figures 12 and 13. There was a rather large effect of Reynolds number on the pressure distributions on the wings. This was especially true of the tip sections which, with an increase of Reynolds number to 15.0 million, maintained their leading-edge low-pressure peaks to higher angles of attack.

The effect of Reynolds number, at a Mach number of 0.24, on the section normal-force coefficient throughout the range of angles of attack is presented in figure 14 for the 5-percent-thick wing and in figure 15 for the 8-percent-thick wing. Here again it is shown, as it was in the force data, that the thinner wing was more affected by a change of Reynolds number. The sections most affected on both wings were those outboard of 60-percent semispan throughout the angle-of-attack range for which tests were conducted. An increase in Reynolds number generally increased the angle at which the tip sections stalled and also increased the values of section normal-force coefficient attained by the tip sections before they stalled.

Effect of Mach Number

Before presenting the spanwise distribution of loading coefficient, it was deemed advisable to compare the total normal force calculated from integration of the measured surface pressures with that from force tests. The limited amount of pressure data obtained on the fuselage made it difficult to determine the amount of lift carry-over on the after part of the fuselage. However, for low values of lift on the linear portion of the lift curve, the agreement between the integrated pressure data and the force data was good, as shown in figure 16.

The variation of the slopes of the theoretical section normal-force curves with Mach number are also presented in figure 16. Before discussing the results of the calculations obtained by the application of both the slender-body theory of Spreiter and the Weissinger theory to the present wings, certain limitations to the theories should be considered. The assumptions upon which the slender-body theory of reference 8 is based make it unreliable in accurately predicting, in the low and middle subsonic Mach number range, the characteristics of wings having aspect ratios as high as those of the present wings. However, as the Mach number approaches a value of 1.0 the accuracy of the theory is greatly increased for all wings of moderate aspect ratio. The accuracy of the Weissinger theory of reference 9 is seriously impaired when it is applied to wings the aspect ratios of which are as low as the apparent aspect ratio (obtained by use of the Prandtl-Glauert rule) of the present wings at the high subsonic Mach numbers. As would be expected from consideration of these limitations of the theories, the slopes of the section normal-force curves computed by the slender-body theory of Spreiter (reference 8) closely approximated the experimental data only at a Mach number of 0.95 and the slopes computed by the Weissinger method (reference 9) were in good agreement only at Mach numbers from 0.24 to approximately 0.70.

In figure 17, a comparison has been made between the spanwise distributions of loading coefficient computed by the slender-body theory, by the Weissinger theory, and that measured for the two wings. The Weissinger method is not directly applicable to the calculation of the spanwise distribution of loading on a wing-body combination as it does not account for the effect of the body. Although this is true the accuracy with which the theory could predict the loading was investigated. If the accuracy was sufficiently good then this method could be used, in preference to the more time-consuming slender-body theory, for predicting the spanwise distribution of loading. It was not unexpected that the Weissinger theory did not predict the loading over the fuselage (see fig. 17) although it predicted with reasonable accuracy the spanwise distribution of loading on the wing. In applying the slender-body theory to computing the theoretical loading coefficients, the fuselage was replaced by a semi-infinite cylinder the radius of which was equal to the maximum radius of the actual fuselage. In this manner the effect of the fuselage was taken into account approximately in the computations. The curves for the experimental data were faired, over the inboard 25 percent of the semispan, so as to be similar in shape to those computed by means of the slender-body theory which does consider the presence of the body. This method of fairing the test data in the vicinity of the fuselage was used in order to get a more accurate estimate of the wing normal force and the spanwise location of the center of pressure. There was little effect of the difference in wing thickness on the spanwise distribution of loading coefficient, and the agreement with the slender-body theory was reasonably good.

There is presented in figure 18 the variation of the experimental and theoretical spanwise location of the center of pressure with Mach number. Both theoretical computations predicted a spanwise location of the center of pressure which was unaffected by Mach number in the range in which the tests were conducted. This prediction was in fairly good agreement with the spanwise locations calculated from the measured pressure distribution; however, the theoretically calculated spanwise locations of center of pressure were inboard of those obtained from test data.

In order to make possible a more complete assessment of the effect of a reduction in thickness on the aerodynamic characteristics of the wings, a summary of aerodynamic characteristics from subsonic force tests previously published in separate reports (references 1 and 2) is presented in figure 19.

The effect of Mach number on the lift-curve slopes of both wings is shown in figure 19(a). There was little change in lift-curve slope with the reduction in wing thickness from 8 to 5 percent.

Figure 19 (b) presents the slopes of the pitching-moment curves for the range of Mach numbers from 0.24 to 0.95. The 8-percent-thick wing had a less rapid rearward movement of the aerodynamic center than the 5-percent-thick wing up to a Mach number of approximately 0.88 above which it moved aft at a faster rate. Both wings had a pitching-moment-curve slope of approximately -0.125 at a Mach number of 0.24, while at a Mach number of 0.95 the value for the thinner wing was -0.180 and that for the 8-percent-thick wing was -0.200.

The variation of maximum lift-drag ratio as a function of Mach number is shown in figure 19(c), and figure 19(d) shows the variation of lift coefficient for maximum lift-drag ratio as a function of Mach number. Both wings had a maximum lift-drag ratio of approximately 12.0 up to a Mach number of about 0.88. Above a Mach number of 0.88 the maximum lift-drag ratio decreased. At a Mach number of 0.95 the maximum lift-drag ratio for the 8-percent-thick wing was about 9.5, while the value for the thinner wing was 16 percent greater, approximately 11.0. The decrease of wing thickness resulted in a reduction of the lift coefficient at which the maximum lift-drag ratio was attained for all Mach numbers at which tests were conducted.

There is presented in figure 19(e) the variation with Mach number of the drag coefficient for several values of lift coefficient. These curves indicate that for lift coefficients of 0.40 and 0.60 the 8-percent-thick wing had less drag than the thinner wing for all Mach numbers below approximately 0.80, while at a lift coefficient of 0.20 there was little difference in the drag. The minimum drag coefficient for the thinner

wing was lower than for the thicker wing at all the Mach numbers at which tests were conducted.

CONCLUSIONS

From the results of wind-tunnel measurements of surface pressures on two triangular wings of aspect ratio 2 the following conclusions may be drawn:

1. The decrease in wing thickness from 8 percent to 5 percent had little effect on the spanwise distribution of loading throughout the test range of Mach numbers.
2. The decrease in wing thickness decreased the angle of attack at which the outer sections of the wing stalled for Mach numbers below 0.80, while at Mach numbers above 0.80 it is indicated that the outboard sections of the thinner wing would have a tendency to stall at the same or slightly higher angles of attack.
3. The theoretical spanwise distribution of loading coefficient, computed by the slender-body theory of Spreiter, was in good agreement with the experimental data. Despite the fact that the Weissinger theory did not account for the fuselage, it predicted reasonably well the spanwise distribution of loading over the exposed portions of the wing.

The results of wind-tunnel tests previously reported in references 1 and 2 and summarized in the present report indicate that the most significant differences in the lift, drag, and pitching-moment characteristics of the two wings are as follows:

1. The decrease in wing thickness from 8 percent to 5 percent had little effect on the maximum lift-drag ratio for the range of Mach numbers below 0.90, while at a Mach number of 0.95 an increase of approximately 16 percent was evident.
2. The decrease of wing thickness resulted in a reduction of the lift coefficient at which the maximum lift-drag ratio was attained for all Mach numbers at which tests were conducted.
3. For lift coefficients over 0.20 and for Mach numbers under 0.80, the decrease in wing thickness from 8 percent to 5 percent resulted in an increase of drag coefficient.

Figure 1.- The model in the 12-foot pressure wind tunnel.

Equation of fuselage ordinates:

$$\frac{r}{r_0} = \left[1 - \left(1 - \frac{2x}{l} \right)^2 \right]^{\frac{3}{4}}$$

*All dimensions shown in inches
unless otherwise noted*

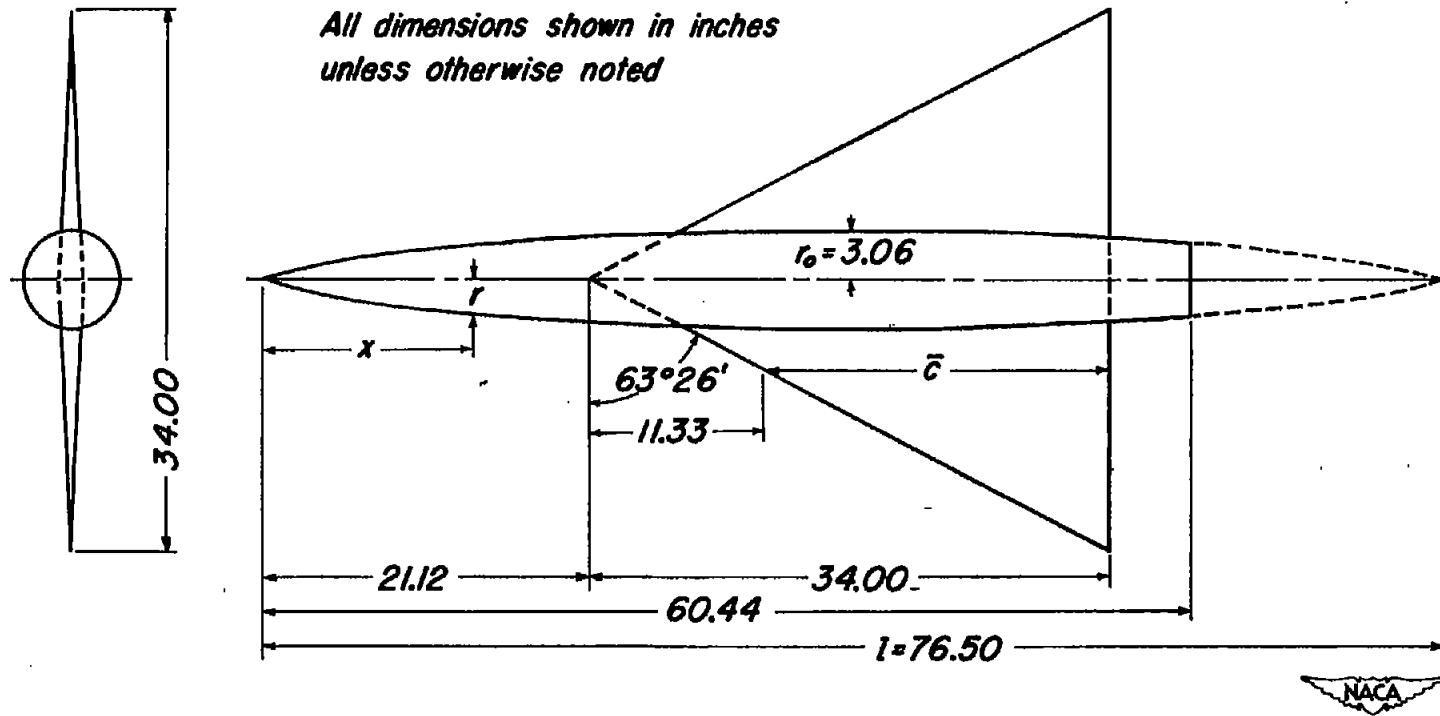

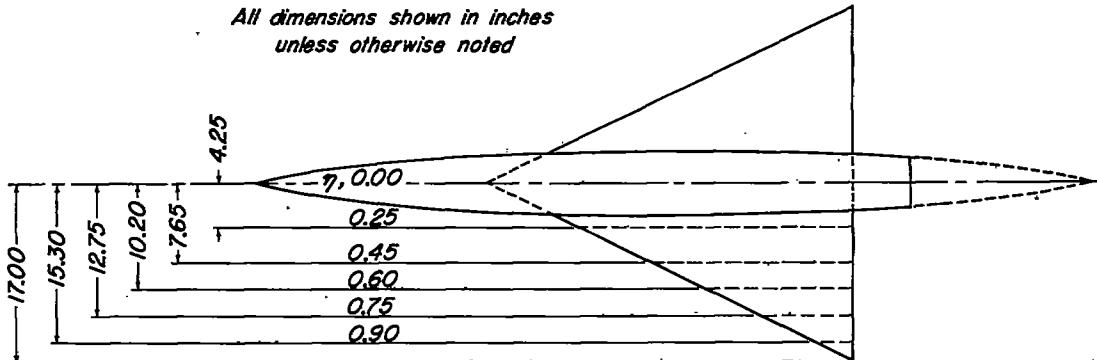

Figure 2.—Plan and front views of the model.

All dimensions shown in inches
unless otherwise noted

(a) Spanwise location.

η , 0.00 (top and bottom center
lines of fuselage);

η , 0.25; η , 0.45; η , 0.60; η , 0.75.

η , 0.90
